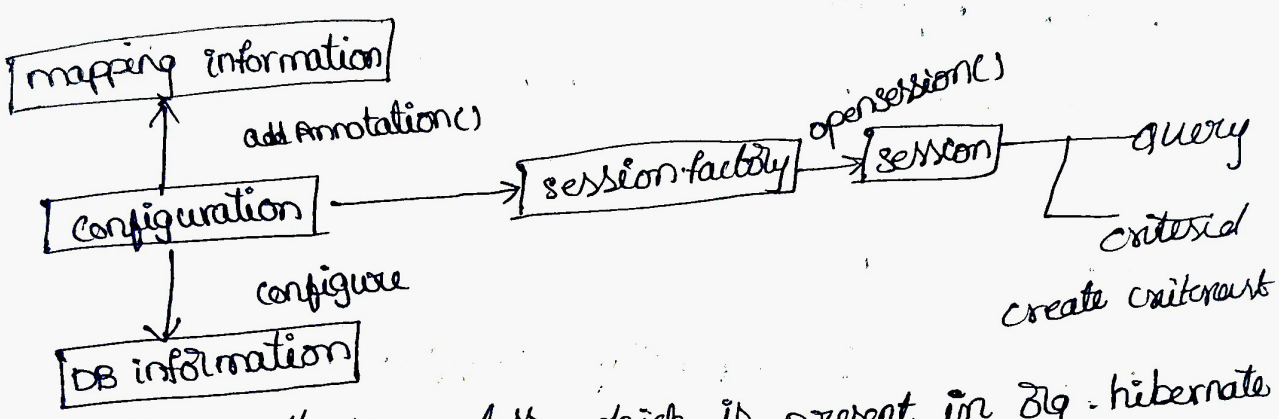
FSD

unit test-4

(1) Explain hibernate architecture in detail?

(2) write about cache management in hibernate?

(1A) hibernate is a framework which is used to develop persistance logic which is independent of database.



configuration : It is a class which is present in org.hibernate.cfg package. It activates hibernate framework

sessionfactory. It is an interface which is present in org hibernate package. It is created based upon session factory object.

Transaction : It is used whenever we perform any operation and based upon that operation there is some change in database.

Query : It is an interface that present inside org.hibernate. It is obtained by calling session.

(20) when the same data is required again hibernate can fetch it from cache instead of re-executing from improving performance and reducing database.

Types

1) First level cache

* enabled by default
* stores all entity that are loaded in same in hibernate session.

2) second level cache

* optional - must be explicitly configured
* shared acrs all sessions created by same session factory

3) query cache

* stores result sets of queries
* requires second level cache to be enabled.
